LINEAR REGRESSION WITH EUROPEAN SALES DATASET

Analysis starts by plotting a heatmap to see correlation values of different variables, later linear regression assumptions are checked one by one, train test split is applied, model is built and various metrics like r-squared and percentage error are measured.

Above heatmap shows the correlation values between variables. SalesPerCapita variable seems to be highly correlated with GDPperHead and EducationSpending, on the other hand ComputerSales has its highest correlation with the Population variable.

When distributions are checked, it is possible to see that all four independent variables are normally distributed and therefore confirms the normality assumption. Later, variance inflation factor test is applied, EducationSpending has a high vif value which causes multicollinearity, thereof it must be dropped. Finally, scatter plots are used to clarify if different independent variables have a linear relationship with two dependent variables SalesPerCapita and ComputerSales. Even though it is not a perfect, linearity can be confirmed and tested.

Data is splitted into train and test datasets and trained using the linear regression model. After testing with various variable combinations, GDPperHead seems to be assisting for both models and Population seems to be helpful for predicting ComputerSales with higher r-squared and lower error percentages.

SalesPerCapita

| cs | Metric | Values |
|-------|-----------------------|-----------|
| R2 0 | R | 0.649993 |
| ed 0 | R2-Adjuste | 0.461527 |
| re 0 | ExplainedVarianceScor | 0.737929 |
| or 25 | MeanAbsoluteErro | 25.364035 |
| or 26 | MedianAbsoluteErro | 26.120741 |
| or 25 | RootMeanSquaredErro | 25.742022 |

| TrueValues | Predictions | Error(%) |
|------------|-------------|-----------|
| 73 | 97.922131 | 34.139906 |
| 75 | 47.680649 | 36.425802 |
| 162 | 131.388259 | 18.896136 |
| 160 | 141.397085 | 11.626822 |

ComputerSales

| Metrics | Values |
|------------------------|-------------|
| R2 | 0.482315 |
| R2-Adjusted | 0.203561 |
| ExplainedVarianceScore | 0.647333 |
| MeanAbsoluteError | 1537.023791 |
| MedianAbsoluteError | 438.597219 |
| RootMeanSquaredError | 2578.384616 |

| TrueValues | Predictions | Error(%) |
|------------|-------------|-----------|
| 813 | 975.591542 | 19.998960 |
| 2847 | 2200.706887 | 22.700847 |
| 9887 | 4778.690818 | 51.666928 |
| 1682 | 1451.098674 | 13.727784 |

For both dependent variables whether r-squared, adjusted r-square or error(%) do not seem satisfying. Mean and median absolute errors are not particularly terrible, but insufficient nonetheless.

On the other hand, root mean squared error is lower than standard deviation of the dataset which is considered as a good sign. ExplainedVarianceScore of ComputerSales does not qualify since it is below 0.70 but ExplainedVarianceScore of SalesPerCapita is 0.73 which is satisfying.

In conclusion; even though some metrics seem adequate, most metrics imply that both models should be improved. It could be a lack of data that causes the poor metrics or lack of specific variables which would violate the assumption of endogeneity in linear regression.
